(54) Title: SYSTEM AND USE FOR CORRESPONDENT BANKING

(57) Abstract

The present invention comprises a system and method for a customer and merchant to perform an on-line, and in some cases, real-time financial transaction from a personal computer or similar processing terminal (10) over a public access communications network (11) utilizing a universally acceptable electronic financial transaction instruction that debits a customer's selected account and notifies a merchant that a credit is due or forthcoming from a service provider. The financial transaction instruction is provided in a secured format for transactions sent over the public access communications network (11), which is external from any other conventional open or closed communications channels used for performing financial transactions.

System and Use for Correspondent Banking**Cross-Reference to Related Applications**

Reference and priority to provisional application no. 60/098,196, filed August 27, 1998 titled, "System for Merchant Function Assumption of Internet
10 Checking and/or Savings Account Transactions" and application no. 09/237,739 filed January 28, 1999 titled, "POS at Home - System and Method for Accessing Banking Account Funds for Internet Transaction" are hereby claimed and the entirety of the subject matter of each pending application is incorporated by reference. Further, reference is made to and application no. 09/_____, filed
15 August 27, 1999 title, "System for Merchant Function Assumption of Internet Checking and/or Savings Account Transactions," the entirety of which is hereby incorporated by reference. Finally, the subject matter of provisional application no. 60/138,607 filed June 11, 1999 titled, "Certificate-Based Credit Account" is hereby incorporated by reference.

20

Field of the Invention

The present invention relates to banking systems and Internet transactions, and more particularly, to a system that allows a customers, merchants, and their respective financial institutions to perform Internet transactions.

25

Background

5 With the increasing commercialization of the Internet, methods of performing payment transactions are becoming well known and new payment methods are desired. In an effort to expand the available sources of payment, methods have been developed to utilize checking account funds to perform Internet transactions.

10 A first conventional method uses "electronic checks" to perform transactions. One example of such an electronic check is the "e-check" process established by the Financial Services Technology Consortium (FSTC). Prior art **Figure 1a** illustrates the system and flow of information used in performing an e-check Internet transaction. In order to participate in an e-check Internet transaction,

15 all of the participants possess the enabling software. Utilizing a processor with a modem **10**, the customer sends customer payment instructions **1** over the Internet **11** to a merchant's Internet terminal **12**. The merchant's terminal **12** attaches the merchant's payment instructions and forms a data message having both the customer's and the merchant's payment instructions **2**. The data message **2** is

20 transmitted over the Internet to the merchant's financial institution server **18** where the server reads the data message and begins settlement procedures with the customer's financial institution **16** over the automated clearing house (ACH) network or electronic check processing (ECP) network using ACH or ECP formatted instructions **3**. Since the merchant's financial institution is initiating the

25 ACH or ECP process, the ACH or ECP instructions **3** are in the form of an ACH or ECP debit request.

5 There are a number of problems, however, associated with current electronic
check methods. For example, there is a delay between the time that the merchant is
notified that the e-check has been returned. This delay may be three or more days. As
a result, the merchant typically must wait a number of days to find out whether or not
the funds are good, thereby delaying fulfillment of the order. As such, utilizing this
10 type of electronic check creates uncertainty for the merchant, as they are unsure if the
electronic check will be paid. Thus, despite the transaction having the appearance to
the customer of being on-line and real-time, it takes several days for the merchant's
account to be charged and for the transaction to be completely processed.

 Even taking into account the delays associated with the e-check payment
15 process, it is still an extremely useful and viable payment method for many types of
goods and/or services but, for a consumer to be able to use this type of e-check, the
consumer must be a member of a financial institution or financial institution that
offers this service. Over the next 5 to 10 years, however, only a few dozen financial
institutions are estimated to participate in issuing electronic checks. Because of this
20 limited participation, the majority of customers will not have access to e-checks from
the financial institution with whom they have an account relationship. Thus, in turn,
the number of customers that a merchant can attract and serve with an electronic
check is limited.

 Additionally, for example, not only must the customer be a member of a
25 participating financial institution, but the merchant must set up procedures for these
types of transactions to deal with the limited number of participating financial
institutions. Due to the limited number of customers who would utilize this payment

5 method, a merchant may be discouraged from expending the time and money to establish such a system.

A second conventional payment system and method as shown in **Figure 1b** begins with the customer modem **10** sending customer payment instructions **1** over the Internet **11** to a merchant's Internet terminal **12**. The merchant's terminal **12**
10 attaches the merchant's payment instructions and forms a data message having both the customer's and the merchant's payment instructions **2**. The data message **2** is transmitted over the Internet to the customer's financial institution server **16** where the server reads the data message and begins settlement procedures with the merchant's financial institution **18** over the automated clearing house (ACH)
15 network using ACH formatted instructions **3**. Since the customer's financial institution is initiating the ACH or ECP process, the ACH instructions **3** are in the form of an ACH credit. An ACH credit is guaranteed since it is issued by the authorizing financial institution. While this method solves the problem of on-line notification to the merchant that the customer has the funds, the method still requires
20 that at least the customer, merchant and the customer's financial institution be equipped to handle Internet formatted transactions and instructions. This is extremely costly due the stringent hardware and software requirements.

In a third conventional payment system, the customer, likely for security reasons, does not choose to have the customer payment instructions go through the
25 merchant. In **Figure 1c**, the customer modem **10** directs the customer payment instructions to the customer financial institution **16** via the Internet **11**. At this point, the customer's financial institution may hide or encrypt the customer's financial

5 information such that it is recognizable only to them or the customer's financial institution removes the customer's information altogether. Along with authorization, the customer's financial institution sends a data message 5 to the merchant terminal via the Internet. After receipt of the data message 5 the merchant may currently process the payment as shown in **Figures 1a** or **1b**. As discussed with reference to
10 the conventional payment methods described above, this payment flow requires that at least the customer, the merchant, and the customer's financial institution be equipped to receive and process Internet formatted transaction requests.

Currently, there is a need for low-cost access to various individual and business accounts held by customers and merchants at multiple financial institutions,
15 to perform financial transactions over the Internet. Most customers access the Internet from remote locations, such as personal computers at home or at a business. Further, many financial institutions, though accessible through networks such as automated teller machine (ATM), ACH, ECP, are not accessible on-line and in real-time by Internet customers and/or merchants wishing to utilize their accounts held within the
20 financial institutions. Finally, the time and expense necessary to put an on-line, real-time payment system into place is currently too great for the majority of financial institutions.

Summary of the Invention

25 Generally, the present invention comprises a system and method for a customer and merchant to perform an on-line, and in some cases, real-time financial transaction from a personal computer or similar processing terminal over a public

5 access communications network utilizing a universally acceptable electronic financial transaction instruction that debits a customer's selected account and notifies a merchant that a credit is due or forthcoming. The financial transaction instruction is provided in a secured format for transactions sent over the public access communications network, which is external from any other conventional open or
10 closed communication channels used for performing financial transactions.

The system and method of the present invention advantageously does not require that there be a traditional financial institution relationship between the customer, the merchant, and their respective service providers/correspondent financial institutions facilitating the on-line financial transactions. Further, the system
15 beneficially does not require the financial institution used by the customer and/or the financial institution used by the merchant to have the capability to perform financial transaction instructions over the Internet. Additionally, the system is compatible with current financial transaction systems, thus making the present financial transaction instruction a universally acceptable on-line financial payment scenario.

20 According to a preferred embodiment, a method of performing a financial transaction between a customer and a merchant, comprises creating customer payment instructions comprising encrypted, electronic representations of a customer transaction amount, account information, financial institution information and security information. The account information identifies various payment accounts, e.g.,
25 checking, savings, money market, at the customer's financial institution and the security information may comprise a personal identification number associated with the identified account information for authorizing its use in an on-line payment

5 transaction. The customer payment instructions are protected by a first secure mechanism, such as an attached digital certificate including a digital signature. The digital signature or other authentication device of the customer provides verification of the identity of the customer and the integrity of the customer payment instruction. The customer payment instructions are electronically delivered to the merchant or in
10 some cases, the customer's financial institution, over a public access network like the Internet.

Merchant payment instructions are appended to the customer payment instructions to create financial transaction instructions. The merchant payment instructions comprise merchant identification and merchant deposit account
15 identification used in performing the transaction. The financial transaction instructions may be protected by a second secure mechanism, such as with encryption and/or by the digital signature of the merchant. The merchant's digital signature provides verification of the merchant's identity and of the integrity of the financial transaction instructions. A digital certificate of the merchant may be appended to the
20 financial transaction instructions, where the merchant's digital certificate provides additional verification of the merchant's identity and the integrity of the financial transaction instructions.

The financial transaction instructions are electronically delivered, such as over the Internet, to at least one service provider offering access to the Internet and other
25 on-line communication channels and public access networks to perform the financial transaction. The service provider removes and reformats the encrypted financial transaction instructions received via the Internet or comparable network and forms a

- 5 recognizable transaction request or message for the participating financial institutions.
- Reformatting the request or message comprises placing the Internet financial transaction request into a format that is recognizable and acceptable to the participating financial institutions. These are formats which are deliverable over conventional networks or channels. The reformatted transaction requests or messages
- 10 are electronically delivered to the participating financial institutions through the appropriate network or channel.

A non-exhaustive list of advantages provided by the foregoing system and method includes: reduction in the amount of equipment and hardware necessary for the facilitation of the payment transaction; increase in the efficiency of Internet

15 payment methods; increase in the number of parties who may partake of Internet purchasing schemes; and reduction in cost associated with Internet payment schemes without compromising security.

Description of the Preferred Embodiments

- The following preferred embodiments of the present invention require that
- 15 at least the merchant and the customer be equipped with Internet payment
instruction software including but not limited to encryption programs as well as
digital certificates for identification and digital signature capability for confirming
message integrity. Further, in a number of the preferred embodiments, one skilled
in the art will recognize that all parties to the transaction must be equipped with
20 some type of enabling software. Prior to discussing the particular payment flow
system and method embodiments, the following provides an explanation of the
possible sources of the software and certificates and the subject matter included
therein.

- In the specific embodiments that follow, the customers and the merchants
- 25 are furnished with digital certificates and software enabling them to transact over
the Internet. These enabling components may be supplied by customer's and
merchant's respective financial institutions or the service providers acting in lieu

Description of the Preferred Embodiments

The following preferred embodiments of the present invention require that at least the merchant and the customer be equipped with Internet payment instruction software including but not limited to encryption programs as well as
20 digital certificates for identification and digital signature capability for confirming message integrity. Further, in a number of the preferred embodiments, one skilled in the art will recognize that all parties to the transaction must be equipped with some type of enabling software. Prior to discussing the particular payment flow system and method embodiments, the following provides an explanation of the
25 possible sources of the software and certificates and the subject matter included therein.

5 In the specific embodiments that follow, the customers and the merchants are furnished with digital certificates and software enabling them to transact over the Internet. These enabling components may be supplied by customer's and merchant's respective financial institutions or the service providers acting in lieu of the customer and merchant financial institutions. In the latter case, the
10 necessary customer and customer's financial institution information is supplied by the customer's financial institution for facilitating a payment out of the funds in the customer's account(s) with the customer's financial institution and similarly, the merchant and merchant's financial institution information is supplied by the merchant's financial institution for facilitating a credit to the merchant's account.

15 The customer information includes at least payment account information and other identifying information that may include name, address, social security number, and e-mail address/URL. The customer's financial institution information includes at least financial institution name and routing transit number. Either the customer's financial institution or the customer's financial institution
20 service provider (CFISP) or even an independent third party service provider then acts as a certificate authority and utilizes the customer and customer's financial institution information to compose digital certificates that are distributed to the customers of the customer's financial institution.

 Similarly, the merchant's financial institution, MFISP, or third-party
25 service provider, collects all of the requisite merchant and merchant financial institution information so as to issue digital certificates containing the requisite

5 merchant and merchant financial institution information. All of the issued digital certificates may follow the X.509 standards for such certificates, recommended by the International Telecommunications Union. Digital certificates are generally known in the electronic communication industry as offering a measure of security to electronic transactions. As applied to a preferred embodiment of the present invention, the digital certificates issued by the service provider, will automatically
10 attach to the payment order sent via the Internet by the customer and merchant upon the institution of the payment software for making an Internet purchase.

In addition to the digital certificates, at least one of customer's financial institution, merchant's financial institution, CFISP, or MFISP must issue enabling
15 payment software to participating customers and merchants. A preferred payment software package of the present invention includes programs/applications for retrieving necessary payment execution information and for creating data messages (e.g., e-mails, Hypertext Markup Language (HTML) pages) under a specially defined file type, a browser plug-in for use with known web browsers
20 (e.g., Netscape® and Internet Explorer®) for recognizing and executing the newly defined files, a program for encrypting data messages, and optionally, the issued digital certificates.

Embodiments of the present invention anticipate that both the customer and the merchant will be creating data messages with the issued payment software.
25 The data message program retrieves and compiles purchase order information from the customer's files, as necessary, for controlling payment transactions. The

5 purchase order information includes payment instructions, an assigned serial
number, the customer's e-mail address and/or URL, the customer's digital
signature, the customer's digital certificate (including the customer's account
number(s) or other security methodology and the customer's financial institution
routing/transit number), and if applicable, the CFISP's data message address (e.g.,
10 e-mail address or URL). Additionally, the merchant's payment software
program/application adds information to the customer's e-mail upon receipt, to
facilitate the payment transaction. This additional information includes a
reference number, the merchant's data message address, the merchant's digital
signature, the merchant's digital certificate (including merchant's account and
15 financial institution information), and if applicable, the MFISP's data message
address.

One skilled in the art will recognize that the following preferred
embodiments necessarily incorporate compatible, interactive enabling software in
order to facilitate at least the Internet transactions between the participating
20 parties.

According to a first preferred embodiment of the present invention, **Figure**
2 provides a system and method enabling a merchant's financial institution server
18 via a merchant's financial institution service provider (MFISP)/correspondent
financial institution server (hereafter "MFISP") **14** to allow a merchant terminal
25 **12** to perform public access network (e.g., Internet) (hereafter "Internet")
transactions. In the first preferred embodiment, the merchant's financial

5 institution is not equipped to handle Internet payment transactions without
employing a MFISP. The payment transaction flow of **Figure 2**, enables a
merchant's financial institution to offer Internet payment services to its merchant
customers.

The Internet transaction is performed with an electronic payment vehicle
10 that allows purchases, exchanges of value, and other payment information or order
instructions to be sent over the Internet. In practice, a first embodiment of this
invention enables a customer modem 10 to transmit customer payment instructions
1 via the Internet 11 to a merchant terminal 12. The merchant terminal 12 adds the
merchants payment instructions and transmits the data message containing both
15 the customer and merchant payment instructions 2a (hereafter "data message")
over the Internet 11 to the MFISP server 14. The MFISP 14 receives the data
message 2a and reformats it into a deposit/credit message 2b that is recognizable
and readable by the merchant's financial institution 18. This reformatting is
necessary since the original data message 2a received by the MFISP is in an
20 Internet or other public access network format, unreadable by the merchant's
financial institution 18. The MFISP transmits the deposit message over a closed
communication channel (CCC) or similar network which is established as a
network for carrying deposit messages to financial institutions. The MFISP may
elect to aggregate one or more payment instructions and send them to the
25 merchant's financial institution according to specific time intervals and/or
maximum number of aggregated deposit messages.

5 In an alternative sub-part of the first preferred embodiment, the CCC could be the Internet but the MFISP 14b is still needed to format the deposit message into a readable Internet format 2b wherein the originating Internet format 2a would be unrecognizable to the merchant's financial institution 18 without the re-formatting.

10 The merchant's financial institution 18 receives and processes the deposit message 2b and initiates settlement with the customer's financial institution server 16 over the traditional ACH or ECP network or similar settlement channel with an ACH or electronic check processing (ECP) debit request 3a. Alternatively, the MFISP is capable of initiating the ACH or ECP debit request 3a as opposed to the
15 merchant's financial institution.

 A second preferred embodiment of the present invention anticipates the situation where the customer's financial institution does not choose to have the customer's account number, or other sensitive information necessary for carrying out the payment transaction, presented to the merchant in any readable form. But,
20 in the second preferred embodiment, the customer's financial institution does not have the necessary decryption tools for reading the encrypted, sensitive information.

 In Figure 3, utilizing a processor with a modem 10, the customer sends encrypted customer payment instructions 1 over the Internet 11 to a merchant's
25 Internet terminal 12. The merchant's terminal 12 attaches the merchant's payment instructions and forms a data message having both the customer's and the merchant's

5 payment instructions 2. The data message 2 is transmitted over the Internet to the merchant's financial institution server 18 where the server decrypts all but the encrypted sensitive information and reads the data message and begins settlement procedures with the customer's financial institution 16 over the automated clearing house (ACH) network or electronic check processing (ECP) network using an

10 ACH or ECP (hereafter "ACH") debit request 3a. In the second preferred embodiment the debit request includes the encrypted sensitive information. The debit request is received by the CFISP 14a which decrypts the sensitive information and transmits the completely decrypted ACH or ECP debit request 3c to the customer's financial institution 16.

15 The third preferred embodiment of the present invention combines the capabilities of the first and second preferred embodiments. Figure 4 enables a customer modem 10 to transmit customer payment instructions 1 via the Internet 11 to a merchant terminal 12. The merchant terminal 12 adds the merchant's payment instructions and transmits the data message containing both the customer

20 and merchant payment instructions 2a (hereafter "data message") over the Internet 11 to the MFISP server 14b. The MFISP 14b receives the data message 2a and reformats it into a deposit message 2b that is recognizable and readable by the merchant's financial institution 18. This reformatting is necessary since the original data message 2a received by the MFISP is in an Internet or other public

25 access network format, unreadable by the merchant's financial institution 18. The MFISP transmits the deposit message over a closed communication channel

5 (CCC) or similar network that is established as a network for carrying deposit messages to financial institutions.

The merchant's financial institution server 18 decrypts all but the encrypted sensitive information and reads the data message and begins settlement procedures with the customer's financial institution 16 over the automated clearing house
10 (ACH) network or electronic check processing (ECP) network using an ACH or ECP (hereafter "ACH") debit request 3a. The debit request includes the encrypted sensitive information. The debit request is received by the CFISP 14a which decrypts the sensitive information and transmits the completely decrypted ACH or ECP debit request 3c to the customer's financial institution 16. In an alternative
15 embodiment, the MFISP 14b performs the composition of the ACH or ECP debit request and transmits it to the customer's financial institution 16. As is shown, the CFISP 14a intercepts the ACH or ECP debit request in order to decrypt the encrypted sensitive information.

In describing a fourth preferred embodiment of the present invention, the
20 following hypothetical situation illustrates the need for such a system and method. A customer, not limited to either an individual or a business, has discovered the Internet to be an appropriate forum in which to locate prospective merchandise and/or services and merchants for the customer's purchasing needs. Instead of being limited to either using credit card information via e-mail; Hypertext Mark-
25 up Language (HTML) pages; or telephonically with all of the debit and credit delays associated therewith; or even more cumbersome, having to actually go to

5 the merchant's location and make the purchase in person, the customer desires to access the customer's accounts with the customer's financial institution on-line and in real-time to satisfy payment to the merchant.

The customer's financial institution, utilizing the method and system of a fourth preferred embodiment of the present invention, is capable of offering this
10 service to the customer through a CFISP without the need for installation of equipment or software at the customer's financial institution and without the need to reveal to the customer, the use of the service provider. In fact, in practice, the presence of the service provider is unknown to either the customer or the merchant. The customer and the merchant both believe that the customer's
15 financial institution is performing all of the steps in the transaction. Consequently, the customer's financial institution increases its marketability with the ability to offer demanded Internet payment services without incurring the costs associated with implementing institution-wide hardware and software.

The fourth preferred embodiment is illustrated in **Figure 5**, wherein, the
20 customer modem **10** sends customer payment instructions **1** over the Internet **11** to a merchant's Internet terminal **12**. The merchant's terminal **12** attaches the merchant's payment instructions and forms a data message having both the customer's and the merchant's payment instructions **2a**. The data message **2a** is transmitted over the Internet to the customer's financial institution server **16** but is first intercepted by
25 the CFISP **14a** where it is reformatted into a recognizable and readable on-line debit message (e.g., ATM) **2b** and then forwarded on to the customer's financial

5 institution server 16 over a CCC. This reformatting is necessary since the original data message 2a received by the CFISP is in an Internet or other public access network format, unreadable by the customer's financial institution 16. The customer's financial institution 16 checks the customer's chosen payment account to verify that the funds are available and sends an on-line, real-time notification 4a
10 to the merchant 12 over the CCC. The CFISP 14a receives the notification authorizing or denying the debit over the CCC and reformats the notification 4b for transmittal over the Internet 11 to the merchant terminal 12. The customer's financial institution or the CFISP, either simultaneous with the notification message or at some later time, will send a guaranteed ACH credit 3b to the
15 merchant's financial institution server 18 in order to facilitate settlement of the transaction. In the case where the CFISP sends the ACH credit, the CFISP is necessarily a financial institution as opposed to being strictly a service provider.

In a fifth preferred embodiment of the present invention, similar to the second preferred embodiment of the present invention, the merchant's financial
20 institution does not choose to have the merchant's account number, or other sensitive information necessary for carrying out the payment transaction, presented to the customer or anyone other participant, other the merchant's own financial institution, in any readable form. But, in the fifth preferred embodiment, the merchant's financial institution does not have the necessary decryption tools for
25 reading the encrypted, sensitive information.

5 In **Figure 6**, utilizing a processor with a modem **10**, the customer sends encrypted customer payment instructions **1** over the Internet **11** to a merchant's Internet terminal **12**. The merchant's terminal **12** attaches the merchant's payment instructions and forms a data message having both the customer's and the merchant's payment instructions **2**. The data message **2** is transmitted over the Internet **11** to
10 the customer's financial institution server **16** where the server sends a notification **4** of authorization or denial of debit from the customer's selected payment account to the merchant over the Internet **11**. The customer's financial institution **16** also decrypts all but the merchant's encrypted sensitive information and reads the data message and begins settlement procedures with the merchant's financial institution
15 **18** by issuing an ACH credit **3b**. In the fifth preferred embodiment the ACH credit includes the encrypted sensitive information. The ACH credit is received by the MFISP **14b** which decrypts the sensitive information and transmits the completely decrypted ACH credit **3d** to the merchant's financial institution **18**.

 A sixth preferred embodiment of the present invention combines the fourth
20 and fifth preferred embodiments of the present invention, wherein each financial institution utilizes a service provider.

 In **Figure 7**, the customer modem **10** sends customer payment instructions **1** over the Internet **11** to a merchant's Internet terminal **12**. The merchant's terminal **12** attaches the merchant's payment instructions and forms a data message having both
25 the customer's and the merchant's payment instructions **2a**. Specific portions of the merchant's payment instructions are encrypted so as not to be readable by any party

5 other than the merchant's financial institution. The data message 2a is transmitted over the Internet to the customer's financial institution server 16 but is first intercepted by the CFISP 14a where it is reformatted into a recognizable and readable on-line debit message (e.g., ATM) 2b and then forwarded on to the customer's financial institution server 16 over a CCC. This reformatting is
10 necessary since the original data message 2a received by the CFISP is in an Internet or other public access network format, unreadable by the customer's financial institution 16. The customer's financial institution 16 checks the customer's chosen payment account to verify that the funds are available and sends an on-line, real-time notification 4a to the merchant 12 over the CCC. The
15 CFISP 14a receives the notification authorizing or denying the debit over the CCC and reformats the notification 4b for transmittal over the Internet 11 to the merchant terminal 12.

Simultaneously, or soon thereafter, the customer's financial institution or the CFISP, decrypts all but the merchant's encrypted sensitive information and
20 reads the data message and begins settlement procedures with the merchant's financial institution 18 by issuing an ACH credit 3b. In the sixth preferred embodiment the ACH credit includes the encrypted sensitive information. The ACH credit is received by the MFISP 14b which decrypts the sensitive information and transmits the completely decrypted ACH credit 3d to the
25 merchant's financial institution 18.

5 A seventh preferred embodiment of the present invention addresses the on-line payment situation wherein the customer seeks to minimize the amount of customer payment and identification information that is available to any entity other than the customer's financial institution. In this particular embodiment, the customer's bank is not capable, without a service provider, of receiving and
10 understanding the customer's Internet payment request.

Referring to **Figure 8**, the customer modem **10** directs the customer payment instructions **1a** to the customer's financial institution **16** via the Internet **11**. The CFISP **14a** then reformats the customer payment instructions into a CCC debit message **1b** that is readable by the customer's financial institution **16** and transmits
15 the CCC debit message over a CCC. The customer's financial institution receives the CCC debit message and either authorizes or denies the debit. Notification of this authorization (or denial as the case may be) plus the remaining or encrypted customer payment instructions **5a** (hereafter "notification+") is sent via the CCC to the merchant terminal **12** but is actually first received by the CFISP **14a** where the
20 notification+ **5a** is reformatted into an Internet format notification+ message **5b**. The CFISP **14a** then transmits Internet notification+ message **5b** to the merchant terminal **12** via the Internet **11**.

An alternative sub-part to the seventh embodiment, has the CFISP **14a** sending the encrypted customer payment instructions **1a** directly to the merchant terminal **12**
25 either with notification of authorization **5b** or without, depending on the relationship established between the CFISP **14a** and the customer's financial institution.

5 The eighth through thirteenth embodiments of the present invention, include the system components and steps recited with reference to the seventh preferred embodiment. Consequently, these will not be repeated in the description of these additional embodiments.

 In the eighth preferred embodiment of **Figure 9**, upon receipt of the
10 Internet notification+ message **5b**, the merchant's terminal **12** attaches the merchant's payment instructions and forms a data message having both the customer's payment instructions (if any) and the merchant's payment instructions **2**. The data message **2** is transmitted over the Internet to the merchant's financial institution server **18** where the server reads the data message and begins settlement
15 procedures with the customer's financial institution **16** by issuing an ACH or ECP debit request **3a**.

 The customer's financial institution retrieves the customer's payment instructions or decrypts the customers portion of the payment instructions included in the ACH or ECP debit request from the merchant's financial institution in order to
20 finalize settlement.

 In the ninth preferred embodiment of **Figure 10**, upon receipt of the notification+ **5b** the merchant terminal **12** adds the merchants payment instructions and transmits the data message containing both the customer and merchant payment instructions **2a** over the Internet **11** to the MFISP server **14b**. The
25 MFISP **14b** receives the data message **2a** and reformats it into a deposit message **2b** that is recognizable and readable by the merchant's financial institution **18**.

5 This reformatting is necessary since the original data message 2a received by the MFISP is in an Internet or other public access network format, unreadable by the merchant's financial institution 18. The MFISP transmits the deposit message over a closed communication channel (CCC) or similar network which is established as a network for carrying deposit messages to financial institutions.

10 The MFISP may batch two or more payment instructions in one deposit message.

The merchant's financial institution 18 receives and processes the deposit message 2b and initiates settlement with the customer's financial institution server 16 over the traditional ACH or ECP network or similar settlement channel with an ACH or ECP debit request 3a. Alternatively, the MFISP is capable of initiating
15 the ACH or ECP debit request 3a as opposed to the merchant's financial institution.

The customer's financial institution retrieves the customer's payment instructions or decrypts the customers portion of the payment instructions included in the ACH or ECP debit request from the merchant's financial institution in order to
20 finalize settlement.

In the tenth preferred embodiment of **Figure 11**, the customer's financial institution 16 does not have the decryption capabilities necessary to decrypt the encrypted customer payment instructions within the ACH or ECP debit request 3a sent by the merchant's financial institution 18. Consequently, the ACH or ECP
25 debit request 3a is received by the CFISP 14a and the encrypted customer payment instructions are decrypted by the CFISP 14a forming a completely readable ACH

5 or ECP debit request 3c prior to being forwarded to the customer's financial institution 16.

In the eleventh preferred embodiment of **Figure 12**, the components and functions of the ninth and tenth embodiments are combined. Upon receipt of the notification+ 5b the merchant terminal 12 adds the merchant's payment
10 instructions and transmits the data message containing both the customer and merchant payment instructions 2a over the Internet 11 to the MFISP server 14b. The MFISP 14b receives the data message 2a and reformats it into a deposit message 2b that is recognizable and readable by the merchant's financial institution 18. This reformatting is necessary since the original data message 2a
15 received by the MFISP is in an Internet or other public access network format, unreadable by the merchant's financial institution 18. The MFISP transmits the deposit message over a closed communication channel (CCC) or similar network which is established as a network for carrying deposit messages to financial institutions.

20 The merchant's financial institution 18 receives and processes the deposit message 2b and initiates settlement with the customer's financial institution server 16 over the traditional ACH or ECP network or similar settlement channel with an ACH or ECP debit request 3a. Alternatively, the MFISP is capable of initiating the ACH or ECP debit request 3a as opposed to the merchant's financial
25 institution.

5 Since the customer's financial institution **16** does not have the decryption capabilities necessary to decrypt the encrypted customer payment instructions within the ACH or ECP debit request **3a** sent by the merchant's financial institution **18**. The ACH or ECP debit request **3a** is received by the CFISP **14a** and the encrypted customer payment instructions are decrypted by the CFISP **14a**
10 forming a completely readable ACH or ECP debit request **3c** prior to being forwarded to the customer's financial institution **16**.

 In the twelfth embodiment of **Figure 13**, upon receipt of the notification+
5b the merchant's terminal **12** attaches the merchant's payment instructions and forms a data message having both the customer's and the merchant's payment instructions
15 **2a**. The data message **2a** is transmitted over the Internet to the customer's financial institution server **16** but is first intercepted by the CFISP **14a** where it is reformatted into a recognizable and readable on-line debit message (e.g., ATM) **2b** and then forwarded on to the customer's financial institution server **16** over a CCC. This reformatting is necessary since the original data message **2a** received
20 by the CFISP is in an Internet or other public access network format, unreadable by the customer's financial institution **16**. The customer's financial institution server **16** initiates settlement by issuing an ACH credit **3b** to the merchant's financial institution server **18**.

 In the thirteenth embodiment of **Figure 14**, the components and functions
25 of the twelfth embodiment are incorporated therein, with the addition component of a MFISP **14b**. The ACH credit **3b** issued by the customer's financial institution

5 16 is actually received by the MFISP 14b wherein encrypted merchant payment instructions are decrypted prior and a completed ACH credit 3d is the transmitted to the merchant's financial institution 18.

 In all of the preferred embodiments, standard public key/private key encryption and other security mechanisms are employed to secure the
10 transmissions of the payment instructions. When the service providers receive incoming messages they perform a variety of security checks including validating the digital certificates to identify the sender and checking the digital signatures to ensure the integrity of the messages. The service providers then decrypt the received messages to retrieve information and re-encrypt them, when appropriate,
15 prior to transmission to their respective financial institutions.

 As discussed previously, one possible source of the security mechanisms (e.g. keys, certificates, signature capability) and enabling software used in practicing the embodiments of the invention is the service providers. The service providers, in addition to issuing the security mechanisms and the software, also
20 provide maintenance and update service with respect to these components of the system. In order to provide a maximum level of encryption security, there may be periodic changes of the keys used in the public/private key system. Similarly, there may be software upgrades and customer or merchant information changes (e.g., new accounts, name changes, address changes). Much of this responsibility
25 stems from the contractual relationship established between the financial institution and the financial institution's service provider. Along these same lines,

5 in addition to the security, software, formatting, and routing services performed by the service provider, the service providers also offer transaction tracking services, investigatory services, and Internet server operation services.

In each of the preferred embodiments discussed above, the service providers are invisible and unknown to the customer and the merchant at all times.

10 Similarly, those employing the service providers, namely, the customer's financial institution and the merchant's financial institution do not utilize the identity of the service provider in performing their respective functions during the transaction. Consequently, although they are employing the services of the service providers, the transaction requests received by their respective servers from the service

15 providers are indistinguishable from any other transaction requests received without the aid of a service provider.

With reference to each of the preferred embodiments, there is no limitation on the type of customer debit accounts or merchant deposit accounts which may be accessed in practicing any of the embodiments of the invention. For example, the

20 debit accounts could include checking, savings, money market, mutual fund, or any comparable account wherein the customer's financial institution recognizes real-time debiting procedures. Merchant deposit accounts include checking, savings, money market, mutual fund, mortgage, loan, credit card, or any comparable account wherein the merchant's financial institution recognizes

25 crediting procedures.

- 5 A significant advantage offered by the preferred embodiments offering an on-line, real-time debit authorization notification to the merchant is that the merchant understands an authorization notification (as opposed to a denial notification) from the service provider to mean that the merchant will receive an ACH credit, within one or two business days, for the amount of the purchase.
- 10 Consequently, the merchant then releases the goods and/or services immediately upon receipt of the authorization notification or informs the customer of the immediate release/rejection of the order (e.g., shipment procedures will be immediately initiated). All of this appears to the customer and the merchant to have occurred on-line and in real-time.
- 15 For the preferred embodiments where there is no on-line, real-time debit authorization notification, the merchant may choose to delay the release of the goods and/or services until a reasonable time period has elapsed and the merchant has not received notification that the debit has been returned. Of course, there are many idiosyncratic factors which play into when the release of goods takes place,
- 20 such as the past course of dealings between the parties, the type of goods and/or services, the purchase price and the identity of the parties. The higher the risk and the greater the loss, the less likely there will be a release without some notification of debit authorization.

 Similarly, the while the merchant's financial institution must credit the

25 merchant's account upon notification of the transaction, this does not translate into immediate availability of funds equaling the credit to the merchant. The

5 merchant's financial institution will consider a variety of factors and financial institution standards in determining when to make the funds available for use by the merchant, including merchant identity, past course of dealings, and amount of the credit.

Further, for the applicable preferred embodiments discussed above, the
10 payment software, depending on the preferences of the issuee (e.g., customer, merchant, customer's financial institution, merchant's financial institution) might include or require many conceivable types of data prior to initiating the on-line payment processes. The various types of data required for completion of an on-line payment transaction are capable of being retrieved and/or added at many
15 different stages in the transaction process by different parties to the transaction. Further there are multiple levels of encryption security mechanisms which may be employed to mask the information from various parties during the transaction process. One skilled in the art recognizes the many possible scenarios and variations.

20 The preferred embodiments of the present invention provide for on-line and in some cases real-time payment transactions over a public access network such as the Internet, without the need for hardware other than standard processors, modems, and servers. With the abolition of the need for magnetic stripe cards or smart cards in performing an on-line debit payment transactions comes the
25 abolition of the need for appropriate card readers and a significant reduction in cost.

5 One skilled in the art will recognize the many additional variations and
embodiments which are contemplated by the invention. For example, in
alternative embodiments, the CFISP could function as the merchant's financial
institution or the MFISP could function as the customer's financial institution. In
these embodiments, the service providers are referred to as correspondent financial
10 institutions since the service providers also offer banking services. Depending on
the specific embodiment, the correspondent financial institution would be able to
either authorize and debit the customers account upon receipt of the data message
if acting in the MFISP/customer financial institution capacity or credit the
merchant's selected deposit account upon receipt of debit authorization if acting in
15 the CFISP/merchant financial institution capacity.

Another variation that is inherent to each of the preferred embodiments is
anticipated multiplicity of parties. For example, the CFISP and the MFISP could
handle as many Internet payment requests from as many customers as the
customers' financial institution services and to whom the appropriate enabling
20 software has been issued. Likewise, the MFISP will process as many merchant
payment requests as it receives for the merchants' financial institution, limited
only by the number of merchants who utilize the merchant financial institution and
are in possession of the enabling software.

This multiplicity variation also applies to multiple financial institutions
25 utilizing a single service provider, each financial institution accepting payment
transactions via the service provider for multiple customers or merchants.

5 Finally, a single service provider could be simultaneously acting as a
CFISP and a MFISP.

 There are additional software inclusions that do not directly affect the
actual formation process of the data messages. The issued software anticipates
multiple users within, for example, a single family or business. For added security
10 and privacy, the software is configured to accommodate multiple passwords for
multiple users. Similarly, the service provider may personalize the software with
multiple digital certificates for multiple users. By way of example, a husband and
wife may hold multiple accounts with a customer's financial institution, some joint
accounts, some individual accounts. Both may wish to utilize the Internet or
15 comparable public access network for making purchases and both may desire to
pay over the Internet with funds from accounts held at the customer's financial
institution. Further, for a large payment amount, one or both of the husband and
wife may desire to split the payment between multiple accounts. The service
provider will issue digital certificates to both individuals which include their
20 respective account information and will require separate passwords or personal
identification numbers (PINs) prior to attaching them to a data message.

 Although the invention has been described with reference to these preferred
embodiments, other embodiments can achieve the same results. Variations and
modifications of the present invention will be apparent to one skilled in the art and
25 the present disclosure is intended to cover all such modifications and equivalents.

1 Claim:

1 1. A method for processing a financial transaction involving a first
2 financial institution, a second financial institution, and a service provider
3 comprising:
4 receiving a first transaction message at the service provider over a
5 first network;
6 formatting the first transaction message at the service provider into a
7 second transaction message for acceptance by the second financial institution; and
8 transmitting the second transaction message from the service
9 provider to the second financial institution.

1 2. A method according to claim 1, wherein the first transaction
2 message comprises a debit request and encrypted data.

1 3. A method according to claim 1, wherein the first transaction
2 message comprises a credit and encrypted data.

1 4. A method according to claim 3, wherein the encrypted data is a
2 debit account number.

1 5. A method according to claim 3, wherein the encrypted data is a
2 deposit account number.

1 6. A method according to claim 1, wherein the first network is selected
2 from the group consisting of an automated clearing house (ACH) network and an
3 electronic check processing (ECP) network.

1 7. A method according to claim 1, wherein the second transaction
2 message comprises a debit request and decrypted data.

1 8. A method according to claim 1, wherein the second transaction
2 message comprises a credit and decrypted data.

1 9. A method according to claim 7, wherein the decrypted data is a
2 debit account number.

1 10. A method according to claim 8, wherein the decrypted data is a
2 deposit account number.

1 11. A system for processing a financial transaction comprising:
2 a first network for transmitting a first data message;

3 a first server for receiving the first data message, decrypting the first
4 data message, and reformatting the first data message into a second data message;
5 a second network for transmitting the second data message; and
6 a second server for receiving the second data message.

1 12. A system according to claim 11, wherein the first data message
2 includes payment instructions.

1 13. A system according to claim 12, wherein the payment instructions
2 include at least a debit account identifier, financial institution identifier, and a
3 deposit account identifier.

1 14. A system according to claim 11, wherein the first network is a
2 public access network.

1 15. A system according to claim 14, wherein the public access network
2 is the Internet.

1 16. A system according to claim 11, wherein the second network is a
2 closed communication channel.

1 17. A system according to claim 11, wherein the second data message
2 includes reformatted payment instructions.

1 18. A system according to claim 12, wherein the reformatted payment
2 instructions include at least a debit account identifier, a first financial institution
3 identifier, and a deposit account identifier.

1 19. A method according to claim 12, wherein the first data message is in
2 a first network format and the second data message is in a second network format.

1 20. A method according to claim 12, wherein the first data message is
2 an electronic mail (e-mail) message.

1 21. A method according to claim 12, wherein the first data message is a
2 hypertext markup language (HTML) page.

1 22. A method according to claim 12, wherein the second data message
2 is formatted as a debit request.

1 23. A method according to claim 12, wherein the second data message
2 is formatted as a credit request.

1 24. A method for processing a financial transaction comprising:
2 transmitting a first data message over a first network;
3 receiving the first data message, decrypting the first data message,
4 and reformatting the first data message into a second data message at a first server;
5 transmitting the second data message over a second network; and
6 receiving the second data message at a second server from the
7 second network.

1 25. A method according to claim 24, wherein the first data message is in
2 a first network format and the second data message is in a second network format.

1 26. A method according to claim 24, wherein the first data message is an
2 electronic mail (e-mail) message.

1 27. A method according to claim 24, wherein the first data message is a
2 hypertext markup language (HTML) page.

1 28. A method according to claim 24, wherein the second data message
2 is formatted as a debit request.

1 29. A method according to claim 24, wherein the second data message
2 is formatted as a credit request.

1 30. A method for processing a financial transaction involving a first
2 user, a first user's financial institution, a second user, a second user's financial
3 institution, and a service provider over multiple networks, comprising:
4 issuing to the first user i) software for directing steps of the financial
5 transaction and ii) at least one certificate for identifying the first user to the service
6 provider, wherein at least one of i) or ii) contains information about the first user's
7 financial institution;
8 receiving at the service provider from the second user via a first network at
9 least the first user's at least one certificate, the second user's financial transaction
10 information, and an encrypted first data message requesting performance of a
11 financial transaction, wherein the financial transaction includes debiting an
12 account of the first user held at the first user's financial institution;
13 verifying an identity of the first user at the service provider via the first
14 user's at least one certificate;
15 decrypting at the service provider the first data message to facilitate
16 performing the financial transaction;
17 formatting at the service provider at least a first portion of the first data
18 message to resemble a financial transaction that is recognizable and readable by
19 the first user's financial institution;
20 encrypting by the service provider the formatted portion of the first data
21 message;

22 forwarding from the service provider the encrypted formatted portion of the
23 first data message to the first user's financial institution via a second network
24 requesting authorization to perform the financial transaction;
25 receiving at the service provider via the second network from the first
26 user's financial institution a response to the request for authorization to perform
27 the financial transaction; and
28 transmitting from the service provider to the second user via the first
29 network a response to the request for authorization to perform the financial
30 transaction.

1 31. A method according to claim 30, wherein the formatted portion of
2 the first data message that is recognizable and readable by the first user's financial
3 institution is a debit message.

1 32. A method according to claim 30, wherein the response to the request
2 for authorization to perform the financial transaction is selected from the group
3 consisting of :

- 4 (1) a denial of authorization to perform the financial transaction,
5 (2) an authorization to perform the financial transaction, and
6 (3) a request for further information.

1 33. A method according to claim 30, wherein the first notification of the
2 response to the request for authorization to perform the financial transaction is
3 contained in a second data message.

1 34. A method according to claim 30, wherein the second network is a
2 closed communication channel.

1 35. A method according to claim 34, wherein the closed communication
2 channel transmits debit requests.

1 36. A method according to claim 34, wherein the closed communication
2 channel is the Internet.

1 37. A method according to claim 30, further comprising:
2 reformatting at the service provider the response to the request for
3 authorization to perform the financial transaction prior to transmitting the response
4 to the second user.

1 38. A method according to claim 30, further comprising:
2 initiating settlement of accounts by the service provider between the
3 first user's financial institution and the second user's financial institution via a

4 third data message over a third network, wherein the third data message is based
5 on at least a second portion of the first data message.

1 39. A method according to claim 38, wherein the third network is an
2 automated clearing house (ACH) network.

1 40. A method according to claim 38, wherein the third data message is a
2 credit.

1 41. A method according to claim 40, wherein the credit is an automated
2 clearing house (ACH) credit.

1 42. A method according to claim 31, further comprising:
2 initiating settlement of accounts by the first user's financial
3 institution between the first user's financial institution and the second user's
4 financial institution via a third data message over a third network, wherein the
5 third data message is based on at least a portion of the debit message.

1 43. A method according to claim 42, wherein the third network is an
2 automated clearing house (ACH) network.

1 44. A method according to claim 42, wherein the third data message is a
2 credit.

1 45. A method according to claim 44, wherein the credit is an automated
2 clearing house (ACH) credit.

1 46. A method according to claim 30, wherein the first network is a
2 public access network.

1 47. A method according to claim 46, wherein the public access network
2 is the Internet.

1 48. A method according to claim 30, wherein the first data message is
2 an electronic mail (e-mail) message.

1 49. A method according to claim 30, wherein the first data message is a
2 hypertext mark-up language (HTML) page.

1 50. A method for processing a financial transaction involving a first
2 user, a first user's financial institution, a second user, a second user's financial
3 institution, and a service provider over multiple networks, comprising:

4 issuing to the first user i) software for directing steps of the financial
5 transaction and ii) at least one certificate for identifying the first user to the service
6 provider, wherein at least one of i) or ii) contains information about the first user's
7 financial institution;
8 receiving at the service provider from the first user via a first network at
9 least the first user's at least one certificate, the second user's financial transaction
10 information, and an encrypted first data message requesting performance of a
11 financial transaction, wherein the financial transaction includes crediting an
12 account of the first user held at the first user's financial institution;
13 verifying the identity of the first user at the service provider via the first
14 user's at least one certificate;
15 decrypting at the service provider the first data message to facilitate
16 performing the financial transaction;
17 formatting at the service provider at least a first portion of the first data
18 message to resemble a financial transaction that is recognizable and readable by
19 the first user's financial institution;
20 encrypting by the service provider the formatted portion of the first data
21 message; and
22 forwarding from the service provider the encrypted formatted portion of the
23 first data message to the first user's financial institution via a second network.

1 51. A method according to claim 50, wherein the formatted portion of
2 the first data message that is recognizable and readable by the first user's financial
3 institution is a credit message.

1 52. A method according to claim 50, wherein the first network is a
2 public access network.

1 53. A method according to claim 52, wherein the public access network
2 is the Internet.

1 54. A method according to claim 50, wherein the first data message is
2 an electronic mail (e-mail) message.

1 55. A method according to claim 50, wherein the first data message is a
2 hypertext mark-up language (HTML) page.

1 56. A method according to claim 50, wherein the second network is a
2 closed communication channel.

1 57. A method according to claim 56, wherein the closed communication
2 channel transmits credit messages.

1 58. A method according to claim 56, wherein the closed communication
2 channel is the Internet.

1 59. A method according to claim 50, further comprising:
2 initiating settlement of accounts by the service provider between the
3 first user's financial institution and the second user's financial institution via a
4 third data message over a third network, wherein the third data message is based
5 on at least a second portion of the first data message.

1 60. A method according to claim 59, wherein the third network is an
2 automated clearing house (ACH) network.

1 61. A method according to claim 59, wherein the third network is an
2 electronic check processing (ECP) network.

1 62. A method according to claim 59, wherein the third data message is a
2 debit request.

1 63. A method according to claim 62, wherein the debit request is an
2 automated clearing house (ACH) debit request.

1 64. A method according to claim 62, wherein the debit request is an
2 electronic check processing (ECP) debit request.

1 65. A method according to claim 51, further comprising:
2 initiating settlement of accounts by the first user's financial
3 institution between the first user's financial institution and the second user's
4 financial institution via a third data message over a third network, wherein the
5 third data message is based on at least a portion of the credit message.

1 66. A method according to claim 65, wherein the third network is an
2 automated clearing house (ACH) network.

1 67. A method according to claim 65, wherein the third network is an
2 electronic check processing (ECP) network.

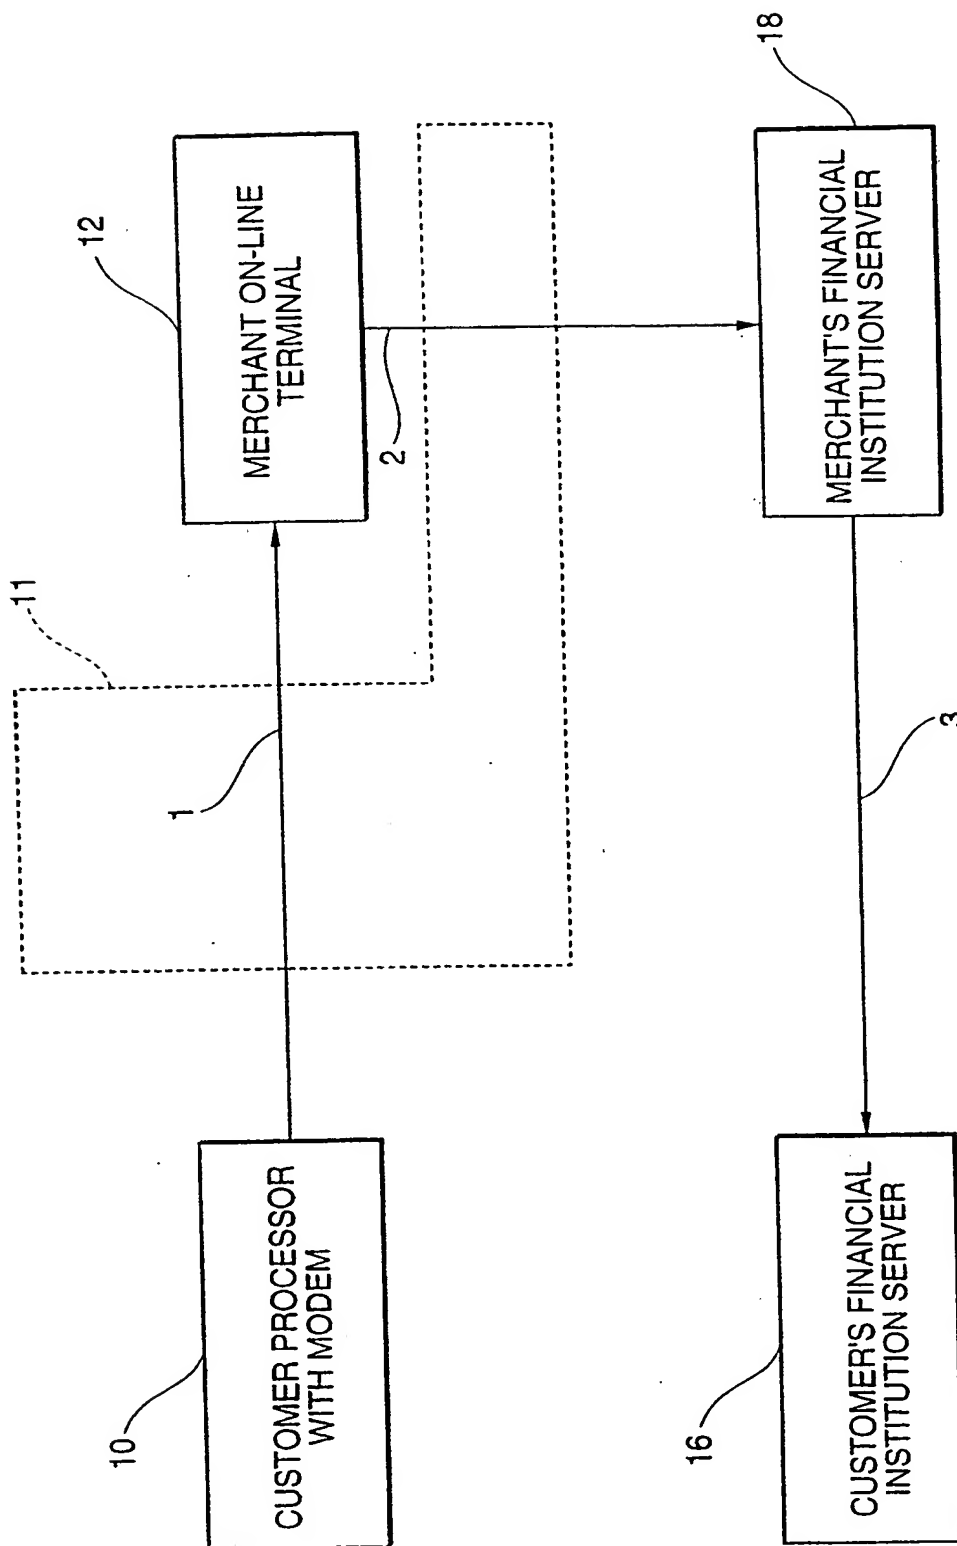

1 68. A method according to claim 65, wherein the third data message is a
2 debit request.

1 69. A method according to claim 68, wherein the debit request is an
2 automated clearing house (ACH) debit request.

- 1 70. A method according to claim 68, wherein the debit request is an
- 2 electronic check processing (ECP) debit request.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US99/19627

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) : G06F 17/60

US CL : 705/44

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 705/44; 705/35; 364/479.02; 380/23

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

DIALOG; APS; DR-LINK; DERWENT; JPO; JAPIO; EUROPEAN PATENT OFFICE; GALE GROUP; EAST

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
	Please See Continuation of Second Sheet.	

Further documents are listed in the continuation of Box C.

See patent family annex.

* Special categories of cited documents:	* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
A document defining the general state of the art which is not considered to be of particular relevance	*X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
E earlier document published on or after the international filing date	*Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*A* document member of the same patent family
O document referring to an oral disclosure, use, exhibition or other means	
P document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search

14 OCTOBER 1999

Date of mailing of the international search report

17 NOV 1999

Name and mailing address of the ISA/US
Commissioner of Patents and Trademarks
Box PCT
Washington, D.C. 20231

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☐ BLACK BORDERS
- ☐ IMAGE CUT OFF AT TOP, BOTTOM OR SIDES
- ☒ FADED TEXT OR DRAWING
- ☒ BLURRED OR ILLEGIBLE TEXT OR DRAWING
- ☐ SKEWED/SLANTED IMAGES
- ☐ COLOR OR BLACK AND WHITE PHOTOGRAPHS
- ☐ GRAY SCALE DOCUMENTS
- ☐ LINES OR MARKS ON ORIGINAL DOCUMENT
- ☐ REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY
- ☐ OTHER: _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
